

Description

METHOD FOR DETECTING AND ELIMINATING ERRORS IN APPLICATION DATA OF AN ELECTRONIC DEVICE

BACKGROUND OF INVENTION

[0001] 1. Field of the Invention

[0002] The present invention relates to a method for detecting application data errors, and more specifically, to a method for detecting errors in application data of an electronic device and restoring the section of memory in which the application data is located to an initial status.

[0003] 2. Description of the Prior Art

[0004] Whenever software is used to run electronic devices, it is highly likely that application data accessed by the software will become corrupted at some point. The user of the electronic device may inadvertently corrupt the application data while using the software. In addition, other hardware problems such as a memory access error may also corrupt

application data.

[0005] Unfortunately, the traditional remedy for fixing the corrupted application data is to return the electronic device to the manufacturer. The manufacturer will then use a tool to reset all application data on the electronic device. However, even if only the application data for one application program was corrupted, the manufacturer must still reset the application data for all application programs. Besides the trouble of sending the electronic device back to the manufacturer and losing the application data, having corrupted data also reduces the user's confidence in the electronic device.

SUMMARY OF INVENTION

[0006] It is therefore an objective of the claimed invention to provide a method of detecting and eliminating errors in application data of individual application programs in order to solve the above-mentioned problems.

[0007] According to the claimed invention, a method of detecting and eliminating errors in application data stored in a section of a memory of an electronic device is disclosed. The method includes providing an application program containing an error checking algorithm in the electronic device, starting the application program to access the appli-

cation data, and executing the error checking algorithm to check for errors in the application data. The application data is erased if the error checking algorithm detects an error in the application data.

[0008] It is an advantage of the claimed invention that the electronic device does not need to be sent back to the manufacturer to eliminate the error in the application data. In addition, only the application data used by a single application program needs to be erased, thereby preserving the application data used by other application programs.

[0009] These and other objectives of the claimed invention will no doubt become obvious to those of ordinary skill in the art after reading the following detailed description of the preferred embodiment, which is illustrated in the various figures and drawings.

BRIEF DESCRIPTION OF DRAWINGS

[0010] Fig.1 is a block diagram of contents of a memory of an electronic device according to the present invention.

[0011] Fig.2 is a table illustrating an example of corrupted application data.

[0012] Fig.3 is a flowchart illustrating detecting errors in application data according to the present invention method.

DETAILED DESCRIPTION

[0013] The present invention embeds an error checking algorithm in multiple software application programs run by an electronic device. The present invention can be used in any electronic device in which a memory is used to store application data that is used by software application programs. These electronic devices include (but are not limited to) mobile phones, personal digital assistants (PDAs), computers, and other such devices. For convenience, the following description will use a mobile phone as an example.

[0014] Please refer to Fig.1. Fig.1 is a block diagram of contents of a memory 2 of an electronic device according to the present invention. The memory 2 stores a plurality of software application programs 4 and application data used in the software application programs 4 is stored in a plurality of sections 10 of the memory 2. For example, the section 10 of the memory 2 labeled "section 1" corresponds to the software application program 4 labeled "software application data 1". Therefore, application data stored in the section 10 of the memory 2 labeled "section 1" is used by the software application program 4 labeled "software application data 1". Examples of the software application programs 4 include a phonebook function or a

calendar function of a mobile phone. In addition, the present invention also embeds an error checking algorithm 6 and a data managing function 8 inside each software application program 4. Each time one of the software application programs 4 is started, the error checking algorithm 6 is automatically run to detect any errors in the application data accessed by the software application program 4. If no errors are found, then the software application program 4 operates normally. Take the application data stored in the section 10 of memory 2 labeled "section 1" as example. If the error checking algorithm 6 in the software application program 4 labeled "software application data 1" detects an error in its application data, the data managing function 8 will erase the application data and reset the corresponding section 10 of the memory 2 to its initial status. No other sections 10 of the memory 2 are reset if only the application data used by the "software application data 1" is erroneous. In other words, it is not necessary to erase the application data for every software application program 4 used in the electronic device, as was necessary in the prior art.

[0015] Please refer to Fig.2. Fig.2 is a table illustrating an example of corrupted application data. The table shows appli-

cation data corresponding to a phonebook software application program. Four names are listed in the phonebook. Normally, each name should have a corresponding phone number associated with the name. However, the name "Sue" does not have a corresponding phone number. This problem could have been caused by a hardware or software problem in the electronic device. When the phonebook software application program is started, the corresponding error checking algorithm 6 would detect this error in the phonebook application data. Thus, the error checking algorithm 6 is able to detect logical errors in the application data that should never occur during normal operation of the corresponding software application program.

[0016] To better understand operation of the present invention, please refer to Fig.3. Fig.3 is a flowchart illustrating detecting errors in application data according to the present invention method. Steps contained in the flowchart will be explained below.

[0017] Step 20:Start the software application program 4;

[0018] Step 22:The error checking algorithm 6 checks for errors in the application data used by the software application program 4;

- [0019] Step 24: If the error checking algorithm 6 detects errors in the application data, go to step 28; if not, go to step 26;
- [0020] Step 26: Since there were no errors detected by the error checking algorithm 6, the electronic device continues to operate the software application program 4 normally;
- [0021] Step 28: Execute the data managing function 8;
- [0022] Step 30: Determine if the user of the electronic device wishes to erase the application data used by the software application program 4; if so, go to step 34; if not, go to step 32;
- [0023] Step 32: Since the error in the application data was not corrected, the electronic device displays an error message the next time the software application program 4 is started to notify the user of the electronic device that there is still an error in the application data;
- [0024] Step 34: The data managing function 8 erases the application data used by the software application program 4 and resets the section 10 of the memory 2 in which the application data is located to its initial status; and
- [0025] Step 36: The electronic device is restarted to let the changes made to the application data take effect.
- [0026] To allow data to be reset conveniently, the memory 2 is preferably a non-volatile memory such as flash memory.

The use of the present invention method for detecting and removing errors in the application data has many advantages over the prior art. For instance, the errors in the application data are detected as soon as the software application program 4 is started. This increases stability of the software application program 4 by reducing the chances of the software application program 4 crashing while accessing a corrupted memory location in the application data. Moreover, since the user is able to erase the application data immediately, there is no need to return the electronic device to the manufacturer. The user will also have increased confidence in the electronic device since errors will be detected and can be rectified immediately.

[0027] Users will commonly go to a service center for upgrading the software running their electronic devices to eliminate any known errors in the software. For users that live in rural areas, it can be a major inconvenience to visit a service center. However, with the present invention, there is less need for the user to immediately upgrade the software since errors can be detected and rectified with the present invention. Therefore, users can choose to wait until a convenient time for upgrading the software on the electronic devices.

[0028] In summary, the present invention uses an error checking algorithm to detect errors in application data used by a software application program. The data managing function then erases only the application data used by that software application program. The section of the memory in which the application data located is reset to its initial status. Therefore, the electronic device does not need to be sent back to the manufacturer to eliminate the error in the application data. In addition, only the application data used by a single application program needs to be erased, thereby preserving the application data used by other application programs.

[0029] Those skilled in the art will readily observe that numerous modifications and alterations of the device may be made while retaining the teachings of the invention. Accordingly, the above disclosure should be construed as limited only by the metes and bounds of the appended claims.
